Abstract—This is the fourth progress report of our group 4 import json Gopher - Group 5 for Machine Learning (CSE523) course project. 5

Index Terms—Time series forecasting, classification, data preprocessing, clustering, graphical models

I. Introduction

For our project, we decided to use the Amazon Bin Images Dataset.

This is originally a Computer Vision dataset. The Amazon 15 Bin Image Dataset contains over 530,000 images and metadata 17 from bins of a pod in an operating Amazon Fulfillment Center. 18

II. BRIEF INSIGHT OF PREVIOUS WORK

After coming up with the modelling of the problem, we 23 generated synthetic data last week. We generated the data 24 similar to the Amazon bin images dataset. On every iteration 26 i.e. on every new row, a product was being added to a list of 10 bins and then the bins were sorted everytime to maintain 27 the bin order. Using the python code, we generated a dataset of 300 bins and 15,000 products 30

III. TASK PERFORMED AND OUTCOMES

In this week, we expanded our dataset in tabular form i.e till last week we had data column in the form of dictionary which was spreaded out into columns of separate bins.

While expanding the data we observed a bug in the dataset we create previous week. In it, our requirement was that each row must represent a volume of input product and the bin state after the product was placed. But, instead our dataset produced results such as at every row the sate of bins gets updated. Which implies that if any product is placed in the bin, then the change will be reflected in the bin state of previous rows too, which was not the likely requirement. Later by making some changes in the script we achieved desired results.

```
import numpy as np
  from tqdm import tqdm
10 def main() -> None:
     for k in tqdm(range(5000)):
         np.random.seed(k)
         arr = []
         bins = dict.fromkeys(range(20), 1)
         vol = np.random.rand(200)
         for i in vol:
             placed = True
              for j in bins:
                  if i < bins[j]:
                      bins[j] -= i
                      bin_no = j
                      break
                  placed = False
             bins = dict(sorted(bins.items(), key=
      lambda x: x[1]))
              arr.append((i, bins.copy(), placed,
          json.dump(arr, open(f"data/{k}.json", "w"))
  if __name__ == "__main__":
     main()
```

The bins in the data were present in a dictionary form and we tabularized to normal form as seen in the image:

```

                                                                                                                                                                                                                                                                        0.023717 0.016353 0.05163 0.003678 0.002267 0.001295
```

Last week we had 15000 rows and we created more data using sythetic data generation libraries like CTGAN. This gave us 1 million rows for 20 bins.

```
#!/usr/bin/env python3
3 import asyncio
```

This week, we also trained a basic Decision tree classifier on the generated data. We split the data into a 95% train and 5% test set. Which gives us around 50,000 rows for the testing dataset. Our output column is '3'. Score of 89.43%

IV. TASKS FOR UPCOMING WEEK

The main tasks to be performed in the upcoming week are:

- 1) Modelling
- 2) Minor tweaking for modelling
